Introducing Today's Project!

What is Amazon Lex?

Amazon Lex is a Chatbot building system. Amazingly useful, it lets you connect other AWS services to your chatbot and reference of request information.

How I used Amazon Lex in this project

Today we added the ability for our chatbot to remmeber (for a short period of time) our Date of Birth so it could utilize this information to check other accounts of ours.

One thing I didn't expect in this project was...

As always, I'm ever impressed with how useful and connected these systems are. I loved being able to quickly reconnect my Lambda function to the new instance and how I could finely tune the memory of the Chatbot.

This project took me...

All together it took me about 30-45 min with testing to complete this project.

Context Tags

Context tags are used in Amazon Lex to store and reference specific information across the conversation.

There are two types of context tags: Input and Output tags. Output tell the chatbot to remember certain details so parts can be used later. Input, checks if specific details are already available before the intent is completed.

I created a context tag called contextCheckBalance. This context tag was created in the intent CheckBalance. This tag stores information about what types of accounts were requested.

FollowUpCheckBalance

I created a new intent called FollowupCheckBalance. The purpose of this intent is to provide the structure for the Chatbot to transition to other account lookups.

This intent is connected to the previous intent I made, CheckBalance, because I used the CheckBalance as the input intent for this FollowupCheckBalance Intent.

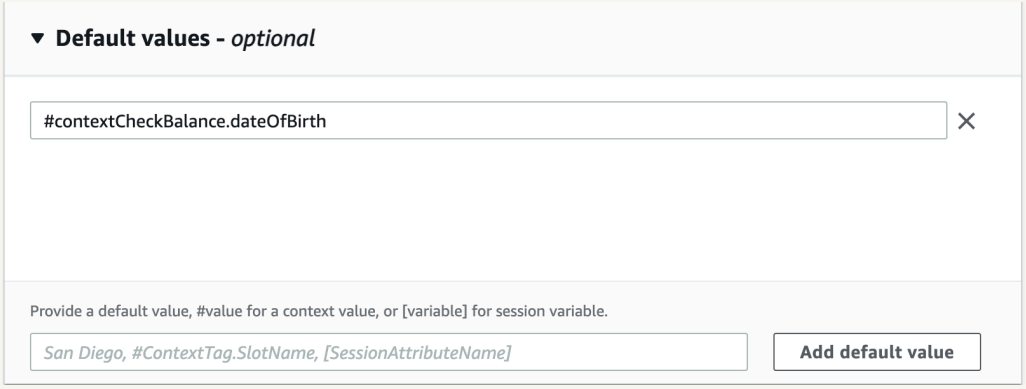
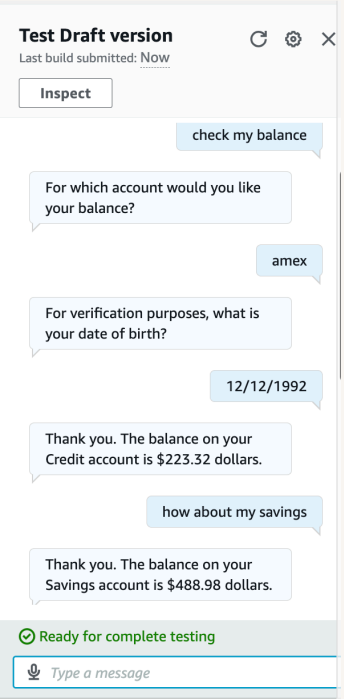
Input Context Tag

I created an input context, contextCheckBalance, that uses the saved value we previously worked with. This step allows the system to remember these details for up to 90 seconds for use within the Lamaba functions we are utilizing.



The final result!

To see the context tags and follow-up intent in action, I had to first engage the CheckBalance intent so it would request my DOB. This would allow the instance to trigger the FollowupCheckBlance intent.


If I had gone straight to trying to trigger FollowUpCheckBalance without setting up any context, the Chatbot would not have the information in its memory of the verification needed (DOB).
